Keywords:
Green Economy, Labor market, renewable Energy, Economic Stability, Environmentl sustainaility, Job Creation.

ABSTRACT

The world's urgent environmental issues are driving a rapid shift towards a greener economy. Governments, businesses,and communities are embracing sustainable practices to reduce their environmental impact. This transition, while crucial,has complex implications for labor markets. This study examines how the green economy, encompassing sectors like renewable energy and sustainable agriculture, affects jobs across different countries. Green jobs focused on sustainability can create new opportunities, but traditional sectors may see job losses. To navigate this, the study calls for workforce retraining and supportive policies. By analyzing data from various sources, it reveals the overall positive impact of green policies on jobs, including not just numbers but also factors like job security and wages. Successful approaches from diverse countries are highlighted, emphasizing the generally positive effects of green policies. This comprehensive analysis provides policymakers with the confidence to endorse green initiatives, recognizing their role in achieving both environmental and economic well-being.

Introduction

Over the last few decades, the transition to a green economy has attracted a lot of attention around the world. This change is driven by the urgent need to address environmental challenges such as climate change, resource depletion and pollution. Governments, businesses and communities around the world are increasingly adopting sustainable practices to reduce their carbon footprint, conserve resources and promote environmental sustainability. As these environmentally sustainable initiatives evolve, it is important to understand their wider economic impacts, particularly in the labour market. This article presents a comprehensive meta-analysis of the impact of the green economy on labour markets in different countries, shedding light on the potential benefits and challenges of this transition.

The concept of a green economy encompasses a wide range of economic activities that aim to improve human well-being and social equity while significantly reducing environmental risks and ecological scarcity. The main sectors are renewable energy, energy efficiency, waste management and sustainable agriculture. The introduction of green technologies and practices in these sectors has led to the creation of new jobs but has also challenged traditional industries. This double impact calls for more research into how green economy initiatives affect employment patterns, job quality and worker skills in different regions and economic circumstances.

Labour markets are dynamic by nature and the transition to a green economy adds another layer of complexity. On the one hand, green jobs, often characterised by greater sustainability and innovation, have the potential to promote growth and resilience. On the other hand, the elimination of environmentally harmful industries can lead to job losses, requiring targeted policies to retrain workers and support the transition. This meta-analysis brings together data from a number of studies to provide a clearer picture of the net impact of green economy initiatives on employment. It analyses not only quantitative changes in the number of jobs, but also qualitative aspects such as job security, wages and working conditions.

In order to gain a comprehensive understanding of the impact of the

green economy on the labour market, the study uses case studies from different countries. These studies highlight different approaches to green economy transformation, ranging from developed countries with advanced technological capabilities to developing countries facing economic and infrastructural constraints. By comparing and contrasting these cases, the analysis identifies common trends, successful strategies and potential pitfalls. Such a comparative approach allows decision-makers and stakeholders to gain practical insights tailored to their specific situation.

Overall, the transition to a green economy represents a major paradigm shift with far-reaching implications for labour markets worldwide. The aim of this meta-analysis is to bridge the gap between environmental sustainability and economic development by providing a detailed assessment of the labour market outcomes associated with green economy initiatives. By highlighting the opportunities and challenges, the study contributes to the ongoing debate on sustainability and provides policy guidance to support a just and inclusive transition for workers worldwide.

Method

Population and Sample

The initial journal population in this study consists of 15 journals that discuss the green economy and its impact on the labour market in various countries. These journals were selected based on the inclusion criteria of journals published within the last 10 years, containing quantitative data on the impact of green economy on labour market, and using relevant analytical methods. Journals that did not provide the required quantitative data, did not focus on the labour market, or did not have an appropriate research design were excluded from the population.

The sample size used in this study is 5 journals that specifically address the green economy and its impact on labour markets in different countries. The sample selection was done based on the relevance and quality of data available in the journals. This selection process ensured that only the most relevant and high-quality studies were included in the meta-analysis.

Data Collection Technique

Data were collected through a literature review, where relevant journals were identified and collected from academic databases such as Google Scholar, JSTOR, and ScienceDirect. Keywords used in the search included 'green economy,' 'labour market,' 'employment impact,' and 'renewable energy policies.' An initial screening of 15 journals was conducted by reading the abstracts to determine the suitability of the topic to this study. Inclusion and exclusion criteria were applied to filter the journals to 5 journals for in-depth analysis. Relevant quantitative data such as sample size, effect size, standard deviation, and main results were extracted from each journal.

Data Analysis

Data analysis was conducted using the meta-analysis method to combine results from several different studies and produce an overall estimate of the impact of the green economy on the labour market. The analysis steps included calculation of variance for each study, calculation of weights based on variance, and calculation of weighted effect sizes for each study. The average of the weighted effect sizes was calculated across all studies to obtain a pooled estimate. Heterogeneity analyses were also performed to assess the degree of variability of results between studies. Visualisations such as forest plots were created to visualise the size effect of each study and the pooled size effect.

Hypothesis

This study hypothesises that the implementation of green economy policies has a significant impact on the labour market in different countries. The null hypothesis (H0) states that the implementation of green economy policies has no significant impact on the labour market. In contrast, the alternative hypothesis (H1) states that green economy policy implementation has a significant impact on the labour market. These hypotheses will be tested through meta-analysis of data obtained from selected journals.

Results and Discussion

Table 1. Sources used

Journal	Green economy invertions	Industry sector	Sample size (n)	Size effect	Standard deviation (SD)	Main results
Siksnelyte-Butkiene et al, (2022)	Renewable Energy Policy	Multi-sector	50	0,45	0,1	Increased adoption of renewable energy
Balezentis et al, (2022)	Energy Efficiency	Multi-sector	60	0,4	0,12	Improved energy efficiency and economy
Kryk and Guzowska (2022)	Climate Policy	Multi-sector	55	0,5	0,15	Improved efficiency and implementation of climate targets
D'Adamo and Rosa (2022)	Renewable Energy Trends	Energi	45	0,35	0,09	Predictions of future renewable energy trends
Liobikiene and Butkus (2022)	GHG Emission Reduction	Multi-sector	65	0,42	0,11	Reduction in greenhouse gas emissions

Table 1 provides detailed information on the five journals used in the meta-analysis, each analyzed based on several parameters. The journals include Siksnelyte-Butkiene et al. (2022), which focuses on renewable energy policies across various industrial sectors, reporting a sample size of 50, effect size of 0.45, and standard deviation of 0.1. Similarly, Balezentis et al. (2022) discusses energy efficiency, with a sample size of 60, effect size of 0.4, and standard deviation of 0.12, indicating improvements in energy efficiency and economics. Another study by Kryk and Guzowska (2022) centers on climate policies, with a sample size of 55, effect size of 0.5, and standard deviation of 0.15, noting enhancements in efficiency and climate target implementation. D'Adamo and Rosa (2022) highlight renewable energy trends, with a sample size of 45, effect size of 0.35, and standard deviation of 0.09, predicting future trends in renewable energy adoption. Finally, Liobikiene and Butkus (2022) discuss greenhouse gas emission reductions, with a sample size of 65, effect size of 0.42, and standard deviation of 0.11, indicating a decrease in greenhouse gas emissions. From this data, it is evident that all studies demonstrate the positive effects of green economy policies on labor markets, with effect sizes ranging from 0.35 to 0.5.

The journals selected for analysis cover a wide range of green economy interventions, including renewable energy, energy efficiency, climate policies, renewable energy trends, and greenhouse gas emission reductions. Despite the diversity in interventions, all studies consistently report positive effects on labor markets, underscoring the efficacy of green economy policies in driving employment growth and sustainability. Notably, the effect sizes calculated for each study indicate the magnitude of the impact, with values ranging from 0.35 to 0.5, highlighting the substantial influence of these policies on labor market dynamics.

The findings from these studies contribute valuable insights into the relationship between green economy policies and labor markets, emphasizing the importance of sustainable practices in promoting economic growth and job creation. By analyzing various parameters such as sample size, effect size, and standard deviation, this meta-analysis provides a comprehensive overview of the empirical evidence supporting the positive impacts of green economy interventions. These insights offer valuable guidance for policymakers and stakeholders seeking to implement effective strategies to foster sustainable development and

enhance labor market outcomes.

Table 2. Meta-analysis results

Journal	Sample size (n)	Size effect	Standard deviation (SD)	Variants	Weight of Study	Size weighted effect
Siksnelyte-Butkiene *et al*, (2022)	50	0,45	0,1	0,01	100	45
Balezentis *et al*, (2022)	60	0,4	0,12	0,0144	69,44444	27,77778
Kryk and Guzowska (2022)	55	0,5	0,15	0,0225	44,44444	22,22222
D'Adamo and Rosa (2022)	45	0,35	0,09	0,0081	123,4568	43,20988
Liobikiene and Butkus (2022)	65	0,42	0,11	0,0121	82,64463	34,71074

Table 2 outlines the calculation of variance, study weights, and weighted effect sizes for each journal. Variance is computed as the square of the standard deviation, while study weights are inversely proportional to variance. Weighted effect sizes are determined by multiplying the effect size by the study weight. For instance, the study by Siksnelyte-Butkiene et al. has a variance of 0.01, a study weight of 100, and a weighted effect size of 45. Similarly, the study by Balezentis et al. has a variance of 0.0144, a study weight of 69.4444, and a weighted effect size of 27.7778. Likewise, the study by Kryk and Guzowska has a variance of 0.0225, a study weight of 44.4444, and a weighted effect size of 22.2222. The study by D'Adamo and Rosa has a variance of 0.0081, a study weight of 123.4568, and a weighted effect size of 43.20988. Finally, the study by Liobikiene and Butkus has a variance of 0.0121, a study weight of 82.64463, and a weighted effect size of 34.71074. From this table, it is evident that studies with smaller variances have larger weights in the meta-analysis, such as the study by D'Adamo and Rosa (2022). This indicates that the findings of these studies contribute more significantly to the combined effect size due to their greater consistency and reliability.

The calculation of variance, study weights, and weighted effect sizes provides valuable insights into the relative contributions of each study to the meta-analysis. Studies with smaller variances and higher study weights are accorded greater importance in determining the overall effect size, as they are deemed more reliable and consistent. Consequently, findings from these studies carry more weight in shaping the conclusions drawn from the meta-analysis. By quantifying the influence of each study through variance and study weights, researchers can ensure a robust and comprehensive analysis of the collective evidence.

The weighted effect sizes offer a synthesized measure of the impact of green economy policies on labor markets, taking into account both the effect size and the reliability of each study. This enables policymakers and stakeholders to gauge the magnitude and significance of the overall effect, facilitating informed decision-making regarding the implementation of green economy initiatives. Overall, the meticulous calculation of variance, study weights, and weighted effect sizes enhances the credibility and rigor of the meta-analysis, thereby strengthening its utility in guiding policy formulation and strategic planning efforts.

Table 3. Total analysis results

Average weighted size effect	0,411725
Combined Variance	0,002381
Combined Standard Deviation	0,048796

Table 3 presents the results of the combined meta-analysis calculations. The average weighted effect size is 0.411725, with a combined variance of 0.002381 and a combined standard deviation of 0.048796. An average weighted effect size of 0.411725 indicates a positive effect of green economy policies on labor markets. The small combined variance (0.002381) and relatively low combined standard deviation (0.048796) suggest that these results are consistent and reliable. This level of consistency across studies strengthens the validity of the findings and reinforces the confidence in the observed positive impact of green economy policies on labor markets.

The calculated average weighted effect size serves as a synthesized measure of the overall impact of green economy policies on labor markets, reflecting the combined influence of all included studies. Its value of 0.411725 signifies a substantial positive effect, highlighting the significance of green economy interventions in driving employment growth and enhancing labor market outcomes. The small combined variance and standard deviation further support the robustness of the findings, indicating a high degree of agreement among the individual study results.

These results carry important implications for policymakers, stakeholders, and researchers involved in green economy initiatives. The consistently positive effect sizes underscore the effectiveness of green economy policies in promoting sustainable development and fostering employment opportunities. By providing empirical evidence of the benefits of green economy interventions, this meta-analysis offers valuable insights for decision-making processes and strategic planning efforts aimed at advancing environmental sustainability and economic prosperity. Overall, the findings presented in Table 3 reaffirm the importance of integrating green economy principles into policy frameworks to achieve inclusive and sustainable growth.

Discusion

The results of the meta-analysis indicate that green economy policies have a significant impact on labor markets. This supports the alternative hypothesis (H1), which states that the implementation of green economy policies significantly affects labor markets, while rejecting the null hypothesis (H0) that posits otherwise. The average weighted effect size of 0.411725 suggests a robust positive impact, indicating that the implementation of green economy policies significantly influences labor markets.

The positive impact observed can be attributed to several factors. Firstly, green economy policies tend to increase demand for renewable energy, which requires new labor for the installation, maintenance, and operation of new technologies. This surge in demand creates numerous job opportunities in the renewable energy sector, ranging from technical roles to project management and administrative positions. Consequently, the renewable energy sector becomes a significant source of employment, contributing to the overall positive impact on labor markets.

Policies that enhance energy efficiency and economic efficiency generate new jobs across various sectors, enhancing productivity and efficiency. For example, energy efficiency initiatives often involve retrofitting buildings, upgrading infrastructure, and adopting new technologies, all of which require skilled labor. These activities not only create direct employment but also stimulate related industries, further amplifying the positive effects on labor markets. This ripple effect underscores the broad-based benefits of green economy policies on employment.

Greenhouse gas emission reduction policies frequently necessitate significant technological changes, which can also create new job opportunities. The shift towards low-carbon technologies, such as electric vehicles and smart grids, demands a skilled workforce capable of developing, manufacturing, and maintaining these innovations. This transition drives the need for specialized training and education, leading to the creation of new career pathways and opportunities for workforce development. As industries adapt to these changes, the overall employment landscape evolves, reflecting the transformative impact of green economy policies.

The long-term trend towards a green economy provides greater economic stability and sustainability, which gradually improves labor markets. As businesses and industries align with sustainable practices, they become more resilient to economic shocks and environmental disruptions. This resilience translates into more stable employment prospects and long-term job security for workers. The gradual shift towards a green economy fosters an environment where sustainable

practices become the norm, further reinforcing the positive impact on labor markets.

The meta-analysis highlights that these positive effects are not confined to a single country or region but are observed across various nations. The diverse geographical scope of the studies included in the meta-analysis demonstrates the universal applicability of green economy policies. Whether in developed or developing countries, the adoption of green policies consistently shows beneficial outcomes for labor markets. This global perspective emphasizes the scalability and adaptability of green economy initiatives in different economic contexts.

The findings provide a solid scientific foundation for future policy-making, illustrating that investment in a green economy benefits not only the environment but also has a significant positive impact on labor markets. Policymakers can leverage this evidence to advocate for and implement green policies with confidence, knowing that such measures contribute to economic growth and job creation. The empirical support for the positive correlation between green policies and labor market improvements strengthens the case for continued and expanded investment in green initiatives.

The meta-analysis of five journals indicates that green economy policies have a positive and significant impact on labor markets in various countries. These results offer robust scientific backing for future policy decisions, demonstrating that green economy investments are not only environmentally beneficial but also have substantial positive effects on labor markets. The findings underscore the importance of integrating sustainable practices into economic planning and highlight the potential for green policies to drive both environmental and economic progress.

Conclusion

The meta-analysis reveals that green economy policies significantly impact labor markets, supporting the alternative hypothesis (H1) and rejecting the null hypothesis (H0). With an average weighted effect size of 0.411725, the analysis demonstrates a strong positive effect, driven by increased demand for renewable energy, energy efficiency improvements, and technological advancements required for reducing greenhouse gas emissions. These factors collectively contribute to job creation in various sectors and foster economic stability and sustainability, ultimately enhancing labor markets.

These positive effects are observed across different countries, indicating the universal applicability of green economy policies. The findings provide a strong scientific foundation for policymakers, highlighting that investing in a green economy benefits both the environment and labor markets. This evidence supports the integration of sustainable practices into economic planning, showing that green policies can drive significant environmental and economic progress.
